#### Abstract

Wax precipitate is one of the most serious issues the oil industry is currently facing, since it can cause some troubles such as increasing of the pressure losses in pipe which subsequently increases the required power for pumpage. To remove this problem, prediction of wax disappearance temperature (WDT) seems necessary. In this study, the pressure influence on the wax disappearance temperature in multi-component mixtures has been surveyed and some correlations have been proposed to predict the wax disappearance temperature instead of using thermodynamic models. The accuracies of the correlations as AARD are $0.30 \%, 0.27 \%$ and $0.68 \%$ for binary, ternary and multi-component mixtures, respectively.

Keywords: Wax precipitation, Thermodynamic model, Wax disappearance temperature (WDT)

## Introduction

Heavy alkane compounds which have been solved in light compounds under specific operating conditions (temperature, pressure and composition) might precipitate as a wax solid phase at the other conditions. Wax precipitation occurs when temperature decreases to the cloud point temperature. Formation of solid layers on the pipe-line walls increases the pressure drop and therefore the power required for pumpage will increase [1].

Changes in temperature, pressure and oil-gas content might create wax. In designing oil-gas processes, thermodynamic models are used to predict wax appearance temperature (WAT) or wax disappearance temperature (WDT) and also the amount of wax [2].

Various thermodynamic models have been used to predict wax appearance temperature and the amount of precipitated wax in atmospheric pressure. Won [3,4] proposed two modified regular solution for wax precipitation. Also Hansen et al. [5] proposed a modified regular solution, which used Flory's theory of multi-component
polymer solutions [6] for activity coefficient of liquid phase. Furthermore Pedersen et al. [7] developed the Won modified model [3] for WAT calculations. Lira-Galeana et al. [8] presented a multi solid phase for wax precipitation. They assumed each solid phase was a pure component. Vafaie-Sefti et al. [9] applied multi-solid phase model (originally developed by Lira-Galeana et al. [8]) to predict the equilibrium phase in the oil mixtures.

Liquid and gas phases were described by using Peng-Robinson EOS [10]. Also Dalirsefat and Feyzi [11] used modified multi-solid phase thermodynamic model (based Lira-Galeana et al. model [8]) for prediction WAT and wax precipitate amount. They utilized Modified PengRobinson (MPR) equation [12] for calculating the fugacity of liquid and gas phases. Coutinho [13] modified a predictive UNIQUAC model (originally developed by Abrams and Prausnitz [14]) for non-ideality of solid and liquid equilibrium.

Also he presented a predictive model [15] for wax formation in jet and diesel fuel.

He used modified UNIFAC for liquid phase and UNIQUAC equation for solid phase [15]. Coutinho et al. [16] and also Coutinho and Ruffier-Me'ray [17] studied wax deposition using experimental and thermodynamics methods.

They used the predictive UNIQUAC model for modeling wax formation in hydrocarbon liquids [16]. Bhat and Mehrotra [18] measured and predicted phase behavior of wax-solvent mixtures using Flory free-volume model [13] for liquid phase and predictive UNIQUAC model [19] for solid phase. Zuo et al. [2] developed solid-solution model to predict wax in crude oils and gas condensates. Esmaeilzadeh et al. [1] investigated various activity coefficient models and showed that predictive Wilson model [20] is appropriate to explain the ideal behavior of the solid phase (prediction of wax precipitate in the atmospheric pressure). Ji et al. [21] succeeded to achieve wax disappearance temperature for binary and multi systems by applying UNIQUAC thermodynamic model. They estimated firstly thermodynamic properties of the normal paraffins for their calculations.

Moreover, Ghanaei et al. [22] have recently investigated a new predictive thermodynamic model for wax formation under high-pressure conditions. By using various thermodynamic models, they achieved WDT for $\mathrm{C}_{14}-\mathrm{C}_{15}$ and $\mathrm{C}_{14}-\mathrm{C}_{16}$ mixtures at various pressures $(0.1-100 \mathrm{MPa})$ and they compared their results with the literature data [23].

In this study, some correlations have been obtained to predict WDT of binary mixtures through using the experimental data reported in the literature [23] and then these correlations have been extended to multi-component mixtures. Without any need to perform thermodynamic calculations and by using the achieved equations, WDT can be estimated for mixtures at different pressures. The predicted results illustrate high accuracy of the correlations.

## 1- Technical development

## 1-1- WDT function

## - Pressure and molecular weight dependency

Ghanaei et al. [22] succeeded to gain WDT for $\mathrm{C}_{14}-\mathrm{C}_{15}$ and $\mathrm{C}_{14}-\mathrm{C}_{16}$ binary mixtures at pressures between 0.1 and 100 MPa using various thermodynamic models and complex thermodynamic calculations. Their results showed good agreement with experimental data in literature [23].

By taking into consideration the data of literature [23] wax disappearance temperature for the pure components ( $\mathrm{C}_{14}$, $\mathrm{C}_{15}$ and $\mathrm{C}_{16}$ ) in various pressures (0.1100 MPa ) showed that WDT increases almost linearly by increasing pressure (Fig. 1).

Figure 1: Variation of WDT vs. pressure for several carbons number (data from Milhet et al. [23])

Fig. (1) illustrates the almost linear increase in WDT as a result of increase in pressure for pure components $\left(\mathrm{C}_{14}, \mathrm{C}_{15}\right.$ and $\mathrm{C}_{16}$ ). On the other hand, trend of WDT changes for the pure components with molecular weight in various pressures has been shown in Fig. (2) (data were extracted from Milhet et al. [23]). By considering the almost linear increase in WDT by increasing the pressure proves this fact that WDT in each pressure can be gained by adding WDT in atmospheric pressure ( $W D T^{\circ}$ ) and one term belonged to the
pressure and the molecular weight. Hence, Eq. (1) was developed to predict WDT of pure components at various pressures. Considering this fact that at 0.1 MPa pressure, wax disappearance temperature equals $W D T^{\circ}\left(\left.W D T^{P}\right|_{P=0.1}=W D T^{\circ}\right)$, therefore $P-0.1$ is used instead of $P$ in the pressure term in order to increase the accuracy of the equation:

$$
\begin{equation*}
W D T^{P}=a M w^{b}(P-0.1)^{c}+W D T^{\circ} \tag{1}
\end{equation*}
$$

By fitting Eq. (1) with the experimental reference data [23], the coefficients $a, b$ and $c$ of Eq. (1) was obtained as follows (Eq. 2):

$$
\begin{equation*}
W D T^{P}=2.0215 M w^{-0.3628}(P-0.1)^{0.9393}+W D T^{\circ} \tag{2}
\end{equation*}
$$

In Eq. (2), Pressure and temperature are in terms of MPa and K respectively.

Figure 2: Variation of WDT vs. molar mass for several pressures (data from Milhet et al. [23])

Figure 3: Variation of WDT vs. molar fraction of $\mathrm{C}_{16}$ in binary mixture ( $\mathrm{C}_{14}-\mathrm{C}_{16}$ ) for several pressures (data from Milhet et al. [23])

## - Composition dependency

Figs. (3) and (4) show the changes in WDT of $\mathrm{C}_{14}-\mathrm{C}_{15}$ and $\mathrm{C}_{14}-\mathrm{C}_{16}$ mixtures on the basis of mole fraction of the heavier substance in $0.1,20,40,60,80$ and 100 MPa (data were extracted from Milhet et al. [23]). It is obvious that trend of WDT changes with mole fraction are so alike in various pressures. WDT changes based on mole fraction have a negative diversion from the straight line that attaches $\left.W D T\right|_{x_{1}}=1$ and $\left.W D T\right|_{x_{2}}=1$ together. By considering the similarity between Figs. (3) and (4) and diagram of $\ln \gamma$ versus mole fraction, an equation similar to RedlichKister [24] with several extra terms was used in this research as presented in Eq. (3):

$$
\begin{array}{r}
\overline{W D T^{p}}=x_{1} x_{2}\left[d x_{1} x_{2}+e x_{1}+f\right]+ \\
x_{1} W D T_{1}^{P}+x_{2} W D T_{2}^{P} \tag{3}
\end{array}
$$

In Eq. (3), $\overline{W D T^{P}}$ is the WDT of the mixture at $P$ pressure, $x_{1}$ and $x_{2}$ are the light and heavy mole fractions and $W D T_{1}^{P}$ and $W D T_{2}^{P}$ are WDT for light and heavy components at $P$ pressure, respectively. After fitting Eq. (3) with the Milhet et al. [23] experimental data (144 data points), $d$, $e$ and $f$ parameters were determined and Eq. (4) was achieved:

$$
\begin{align*}
\overline{W D T^{P}} & =x_{1} x_{2}\left[40.0764 x_{1} x_{2}-53.5956 x_{1}\right. \\
& +2.5806]+x_{1} W D T_{1}^{P}+x_{2} W D T_{2}^{P} \tag{4}
\end{align*}
$$

Eq. (4) was used to predict the WDT of the binary mixture.

Although Eq. (3) has been presented for binary mixtures, it can also be used for ncomponent mixtures. To generalize Eq. (3) to the multi-component mixtures, ( $1-x_{1}$ ) was replaced with $x_{2}$ in Eq. (3). Also, the last two terms of the Eq. (3) was shown with $\sum_{i=1}^{n} x_{i} W D T_{i}^{P}$. Eq. (5) shows the generalization of Eq. (3) for multicomponent mixtures:

$$
\begin{align*}
\overline{W D T^{P}}= & x_{1}\left(1-x_{1}\right)\left[h x_{1}\left(1-x_{1}\right)+\right. \\
& \left.k x_{1}+m\right]+\sum_{i=1}^{n} x_{i} W D T_{i}^{P} \tag{5}
\end{align*}
$$

where $x_{1}$ is the lightest component that can form wax precipitate. For determination the parameters of Eq. (5), the data of Metivaud et al. [25] were used ( 29 data points). These data are containing ternary mixtures of several hydrocarbons. After fitting of Eq. (5) with these data, $h, k$ and $m$ parameters were determined as follows:

$$
\begin{align*}
& \overline{W D T^{P}}=x_{1}\left(1-x_{1}\right)\left[23.2 x_{1}\left(1-x_{1}\right)-\right. \\
& \left.4.4631 x_{1}-10.8033\right]+\sum_{i=1}^{n} x_{i} W D T_{i}^{P} \tag{6}
\end{align*}
$$

Figure 4: Variation of WDT vs. molar fraction of $\mathrm{C}_{15}$ in binary mixture ( $\mathrm{C}_{14}-\mathrm{C}_{15}$ ) for several pressures (data from Milhet et al. [23])

## 1-2- Prediction of WDT

Eqs. (2) and (4) were used to predict the WDT of binary mixtures. Moreover, for prediction of wax disappearance temperature of multi-component mixtures Eqs. (2) and (6) were used. The only experimental data which is required for these calculations is WDT of the pure components at atmospheric pressure (equations in Appendix A of Ji et al. [21] are used to estimate it). The calculations procedure to predict WDT of mixtures is as follows:

- First, $W D T^{P}$ is calculated for the pure component in the desired pressure (Eq. (2)).
- For binary mixtures: by using $W D T_{1}^{P}$ and $W D T_{2}^{P}$ and also the mole fraction of each component of the mixture, WDT is calculated for the mixture (Eq. (4)).
- For multi-component mixtures: by using $W D T_{i}^{P}$ and $x_{i}$ for each component of mixture WDT is calculated (Eq. (6)).

## 2- Results and discussion

## 2-1- Binary systems, various pressures

The results of calculating WDT through using various thermodynamic models for binary systems of $\mathrm{C}_{14}-\mathrm{C}_{15}$ and $\mathrm{C}_{14}-\mathrm{C}_{16}$ were mentioned in this section. Tables (3) to (12) of Ghanaei et al. [22] were shown WDT of $\mathrm{C}_{14}-\mathrm{C}_{15}$ and $\mathrm{C}_{14}-\mathrm{C}_{16}$ mixtures and also their Average Absolute Relative Deviation (AARD). The results prove that the AARD of 'new model' is less than any other models (the models who studied by Ghanaei et al. [22]) and equals to $0.36 \%$ [22]. The results of WDT calculations by using Eqs. (2) and (4) for $\mathrm{C}_{14}-\mathrm{C}_{15}$ and $\mathrm{C}_{14}-\mathrm{C}_{16}$ systems were shown in Tables (1) and (2), respectively. The Average Absolute Relative Deviation (AARD) of the models presented in Ghanaei et al. [22] work and 'our correlation' were summarized in Table (3). As shown in this Table, AARD for $\mathrm{C}_{14}-\mathrm{C}_{15}$ and $\mathrm{C}_{14}-\mathrm{C}_{16}$ mixtures are $0.25 \%$ and 0.33 $\%$, respectively. So the WDT average error for the method proposed by this article is equal to $0.30 \%$ which is less than investigated methods mentioned in Ghanaei et al. [22] work.

## 2-2- Multi-component systems, atmospheric pressure

The ternary data of Metivaud et al. [25] $\left(\mathrm{C}_{14}-\mathrm{C}_{15}-\mathrm{C}_{16}, \mathrm{C}_{16}-\mathrm{C}_{17}-\mathrm{C}_{18}, \mathrm{C}_{18}-\mathrm{C}_{19}-\mathrm{C}_{20}\right.$ and $\mathrm{C}_{19}-\mathrm{C}_{20}-\mathrm{C}_{21}$ ) were used for evaluation the accuracy of 'our correlation'. The result of calculating WDT at atmospheric pressure for ternary mixtures, by using Eqs. (2) and (6) are monitored in Tables (4) to (7).

Ji et al. [21] have investigated several models (ideal solid solution, multi-puresolid, Continuo's UNIQUAC and HWWAX) for ternary mixtures of $\mathrm{C}_{14}-\mathrm{C}_{15}-$ $\mathrm{C}_{16}$ and $\mathrm{C}_{18}-\mathrm{C}_{19}-\mathrm{C}_{20}$ in atmospheric pressures. They used the some data of Metivaud et al. [25] for comparison the results. To perform thermodynamic calculations, they first estimated the thermodynamic properties of the components and then WDT.

Table 1: Results of WDT calculations in $K$ for the $\left\{(1-x) n-C_{14}+x n-C_{15}\right\}$ binary system as a function of pressure using 'our correlation' (experimental data from Milhet et al. [23])

## 2-3- Multi-component systems, various pressures

By using Daridon et al. [26] experimental data the more accurate investigation of ' $H W W A X$ ' thermodynamic model [21], the predictive model of Ghanaei
et al. [22] ('new model') and the proposed 'our correlation' (Eq. (6) of this work), have been performed. In Daridon et al. [26] work, hydrocarbon mixtures were studied with different components and compositions and the experimental data of WDT has been
reported for each mixture at various pressures [26]. In this study, the data of Daridon et al. [26] (Tables (3) and (4) of this literature) was used for validation of the proposed correlations.
Tables (9) to (11) show the results of WDT calculations for mixtures in various pressures using 'new model' [22], 'HWWAX' thermodynamic model [21] and the proposed 'our correlation', respectively. The AARD for each of these methods is also mentioned in these Tables. The AARD of calculating WDT is $0.79 \%, 0.79 \%$ and $0.68 \%$ for the predictive model ('new model') of Ghanaei et al. [22], 'HWWAX' thermodynamic model [21], and also the proposed 'our correlation' respectively. 'HWWAX' thermodynamic model can't properly predict WDT for mixtures with high number of components (Table 10). The algorithm of WDT calculations for 'HWWAX' thermodynamic model, 'new model' and also the equations required for estimating thermodynamic properties are presented in Ji et al. [21] and Ghanaei et al. [22] works. As it is obvious, the equations proposed by this article have an outstanding accuracy and its AARD is equal to $0.68 \%$ for multi-component mixtures.

## 3- Conclusion

The pressure effect on Wax Disappearance Temperature of multicomponent mixtures has been surveyed in this article. First, some- but not so complexcorrelations were achieved for binary mixtures through fitting experimental data. Then the achieved equations were generalized to multi-component mixtures. This method enjoys a unique accuracy in addition to avoiding any need for complex and long thermodynamic calculations and
has less average absolute relative deviation than other previously investigated thermodynamic methods. The average absolute relative deviation result of WDT by using 'our correlation' for binary mixtures at various pressures, ternary mixtures at atmospheric pressure and multicomponent mixtures at various pressures are $0.30 \%, 0.27 \%$ and $0.68 \%$, respectively.

## Nomenclature

| a, b, c | parameters of equation 1 |
| :---: | :---: |
| d, e, f | parameters of equation 3 |
| h, k, m | parameters of equation 5 |
| Mw | molecular weight |
| $n$ | number of component |
| $P$ | pressure, MPa |
| $W D T^{\circ}$ | wax disappearance temperature in atmospheric pressure, K |
| $W D T^{P}$ | wax disappearance temperature in P pressure, K |
| $\overline{W D T^{P}}$ | wax disappearance temperature of mixture in P pressure, K |
| $x$ | molar fraction |
| Subscripts |  |
| 1 | light component |
| 2 | heavy component |
| $i$ | ith component |
| Acronyms |  |
| AARD | average absolute relative deviation $\left[\equiv(100 / m) \sum_{i=1}^{m} \mid \exp _{i}-\text { calc }_{i} \mid / \exp _{i}\right], \%$ |
| ARD | absolute relative deviation $[\equiv$ $\left.\sum_{i=1}^{m}\left\|\exp _{i}-\operatorname{calc}_{i}\right\| / \exp _{i}\right], \%$ |
| HWWAX | Heriot-Watt wax |
| MPR | modified Peng Robinson |
| NDP | Number of data point |
| PR | Peng Robinson |
| UNIFAC | universal functional activity coefficient |
| UNIQUAC | universal quasi-chemical |
| WAT | wax appearance temperature, K |
| WDT | wax disappearance temperature, K |
